

Time for a new paradigm

a network perspective on psychopathology

Psychopathology networks

cross-sectional

So, networks!

But what is the network structure of depression?

We need data

Empirical networks

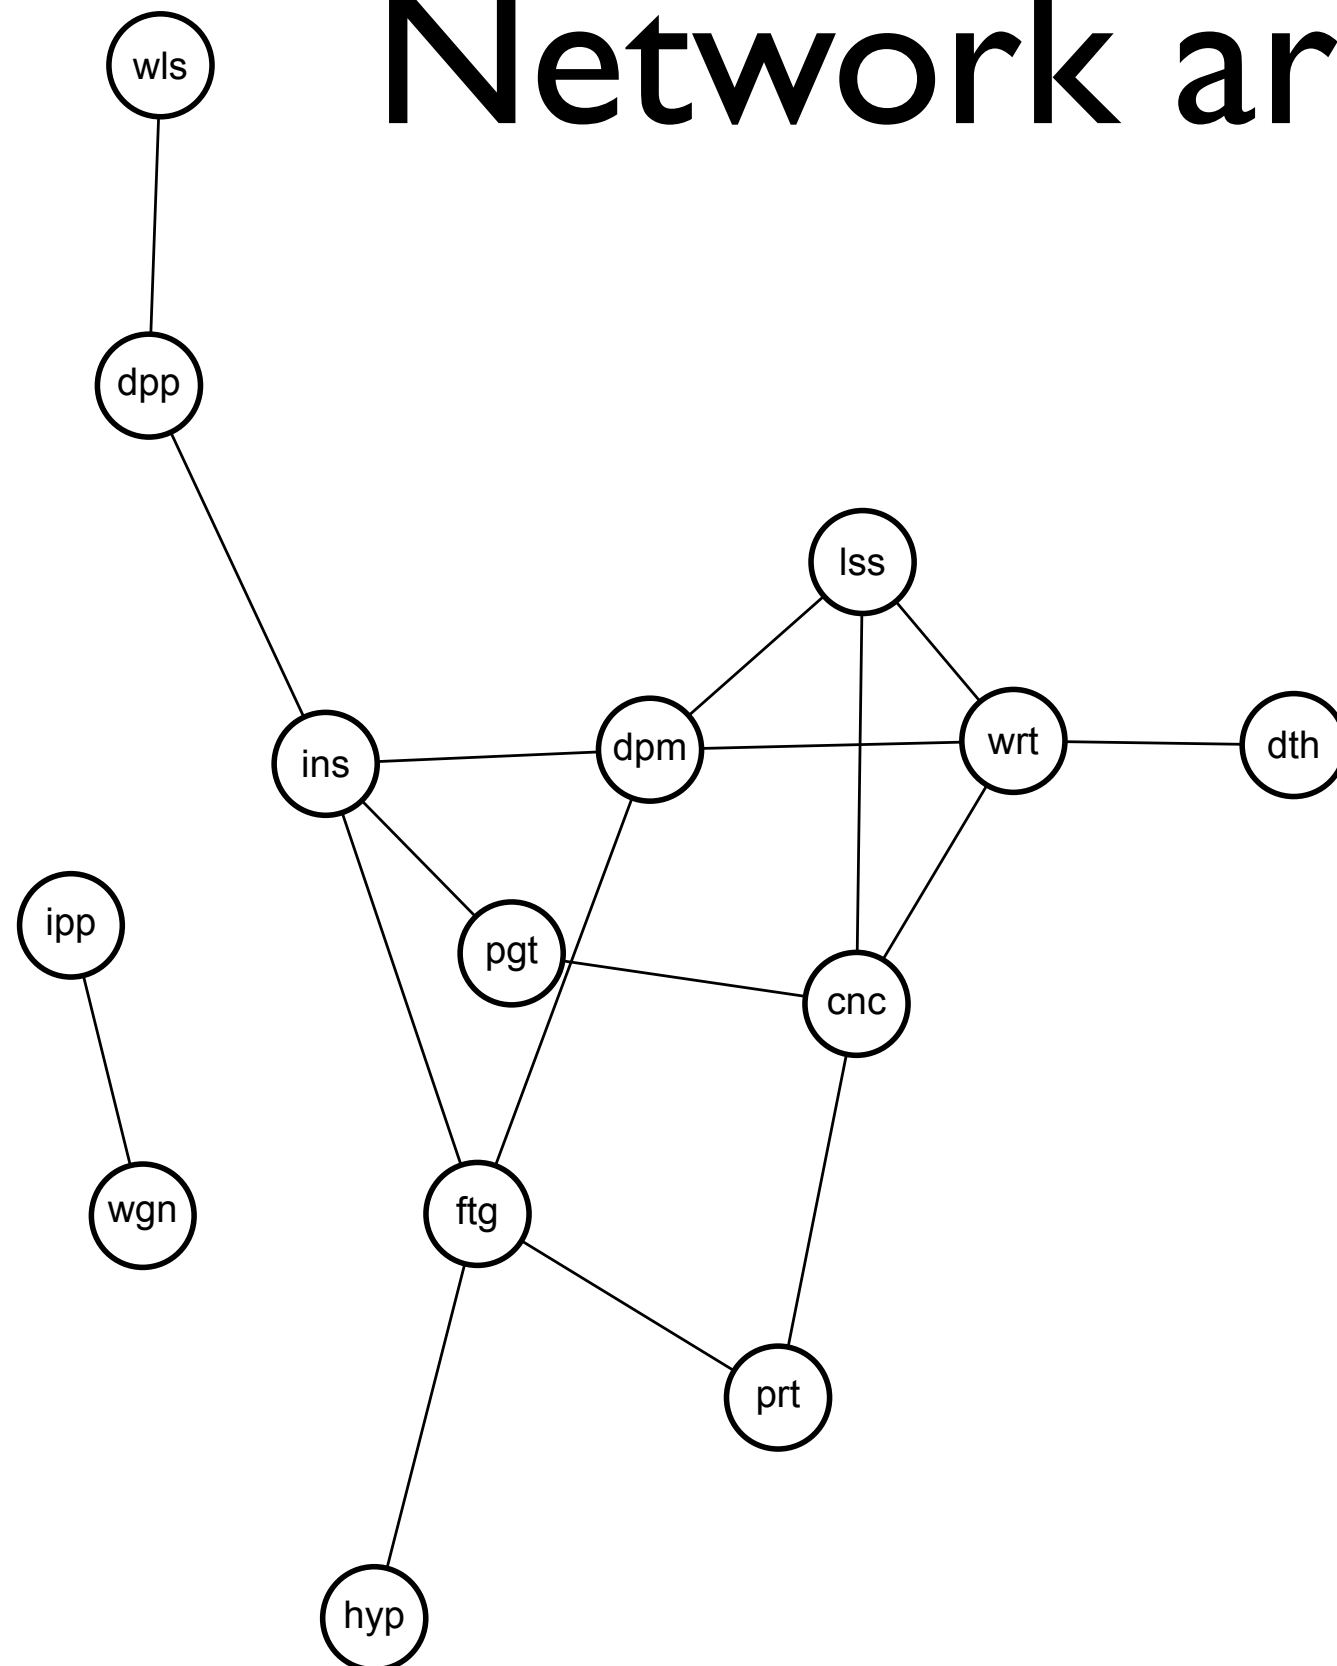

Based on empirical data

- VATSPUD study (Kendler & Prescott, 2006)
- > 8000 participants

Identification of node set:

- Symptoms of major depression in the DSM-IV

Network architecture

Symptoms (degrees)

dpm=depressed mood (4)
lss=loss of interest (3)
wls=weight loss (1)
wgn=weight gain (1)
dpp=decreased appetite (2)
ipp=increased appetite (1)
ins=insomnia (4)
hyp=hypersomnia (1)
pgt=psychomotor agit. (2)
prt=psychomotor ret. (2)
ftg=fatigue (4)
wrt=worthlessness (4)
cnc=concentration loss (4)
dth=thoughts of death (1)

Network parameters

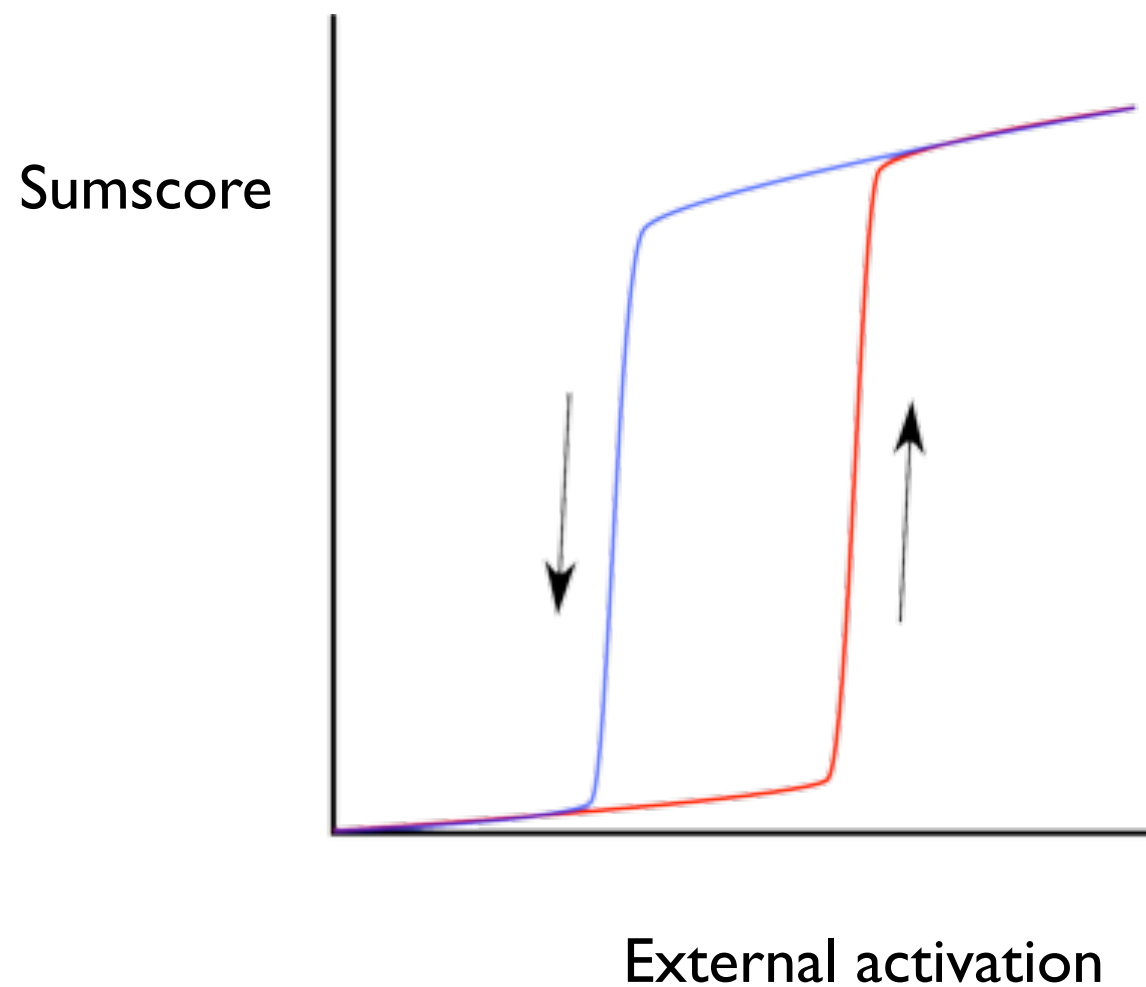

Logistic regression of
symptom on
neighboring symptoms
in the network gives
a) threshold
b) reactivity of symptom
wrt neighbors = slope

Simulations

- Imagine that connected nodes can ‘infect’ each other, so that symptoms can spread through the network
- Two ways to manipulate network:
 - putting network under stress
 - changing network vulnerability (diathesis):
increasing/decreasing connection strength

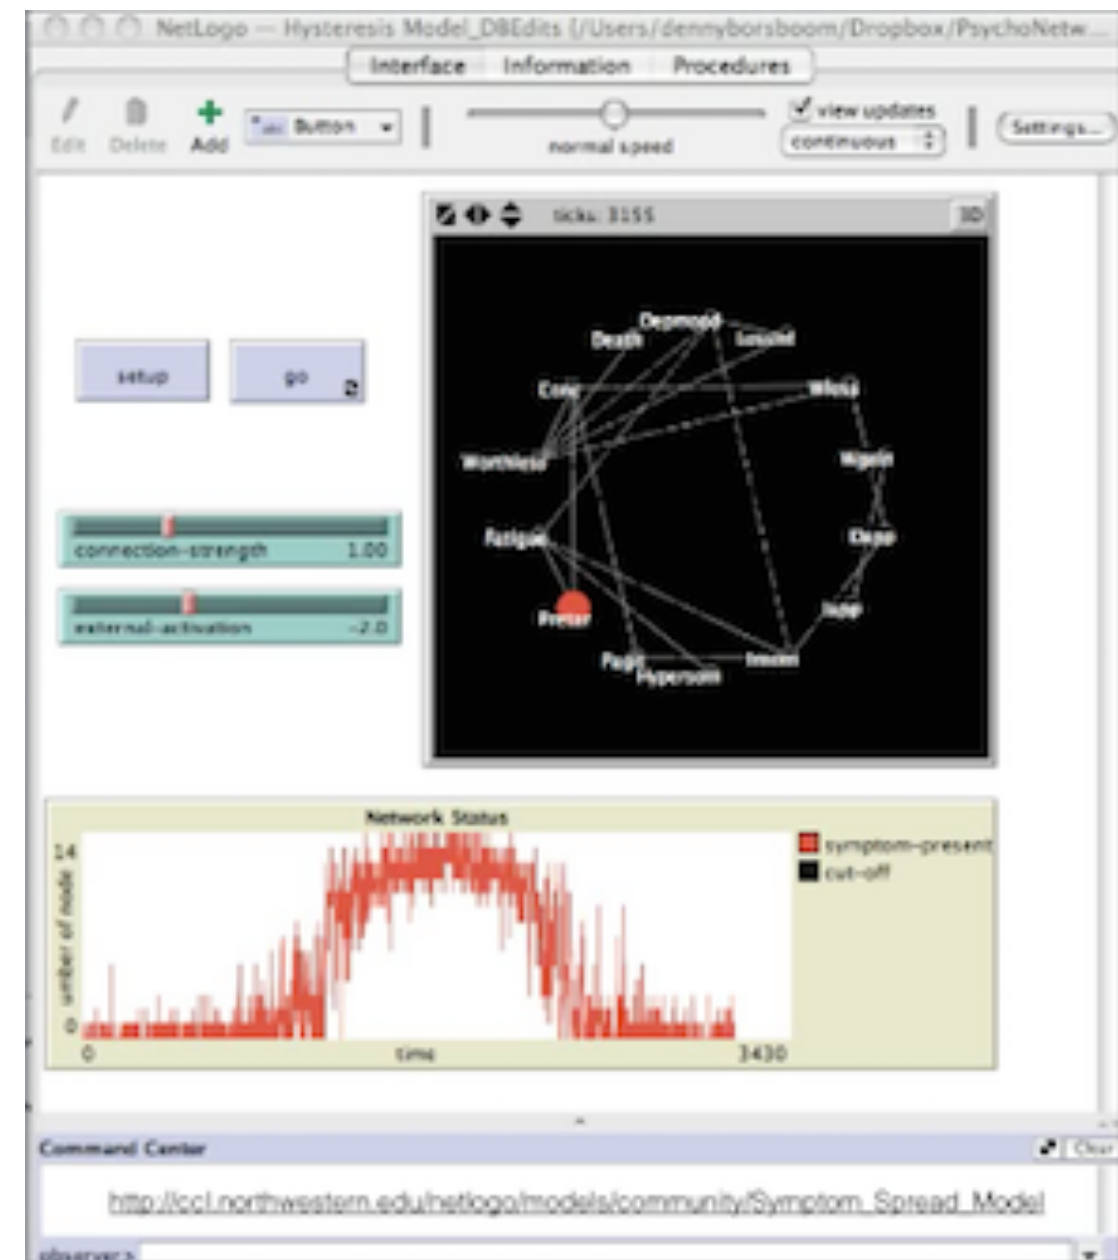

Hysteresis

- Bimodal behavior
- Sudden changes between modes
- Transitions at different values of control factors (depends on where you come from)
- Inaccessible zone

Simulations show...

- ... that dynamics of networks are associated with phase transitions
- ... that connection strength is a plausible mechanistic realization of vulnerability ('diathesis')
- ... that the presence of hysteresis potentially explains resistance to treatment in severe cases
- ... that findings are robust to variations on parameter settings

Physics meets psychopathology

Issues with current methods to estimate network:

- significance level
- arbitrary cut-off

A new method: eLasso

- based on Ising model
- ℓ_1 -regularized logistic regression (Ravikumar, Wainwright & Lafferty, 2011)
- Goodness-of-fit measure (*extended BIC*) (Chen & Chen, 2008)

Correlation graph

Partial correlation graph

Physics meets psychopathology

Ising model

- to explain ferromagnetism
- small dipoles (spins) can be 'spin up' (+ 1) or 'spin down' (- 1)
- can be generalized to other *objects* in a network (voter, neuron, tree)
- objects/variables can interact, but only with direct neighbors

-	-	-	+	-
+	+	-	-	-
-	-	+	-	-
+	+	+	-	-
-	+	-	+	+

Simulation study

- Create a network
- This is the “true” network
- Generate data according to Ising model
- Use simulated data to estimate network (with R package **IsingFit**)
- Does estimated network look like “true” network?

Application to real data

- NESDA (Netherlands Study of Depression and Anxiety)
 - n=2981
 - Deelnemers via huisartsenpraktijken en GGZ-instellingen mét en zonder klachten
- IDS (Inventory of Depressive Symptomatology)
 - 27 depression and anxiety items

Psychopathology networks
cross-sectional

Centrality measures

- Node strength: weighted sum of connections
- Betweenness: how often node appears on (shortest) path between nodes in network
- Clustering coefficient: the capacity of the node to be a hub

Psychopathology networks

cross-sectional

Interesting questions

- Is having 'important' symptoms predictive for having MDD later?
- Participants with MDD at baseline: does group that recover have a different network than those that do not recover?
- How are biomarkers involved in the depression network?
- Does micro-intervention based on individual network work?

Psychopathology networks

longitudinal

Contact process model

Two independent Poisson processes:

- infection (with parameter λ)
- recovery (with parameter μ)

Ratio $\rho = \lambda / \mu$

$\rho > 1$: supercritical case
process survives forever

What do we need?

- binary multiple observations
- network structure
- parameters for ratio ρ
(λ and μ)

Contact process model

- **Network structure: eLasso** (adjusted version of `IsingFit` package in R)
- **parameter: Percolation Indicator (PI)**

Contact process model

- **Network structure: eLasso** (adjusted version of `IsingFit` package in R)
- **parameter: Percolation Indicator (PI)**

$$r(x, i; \lambda, \mu) = \lambda k_{i-1}(x)(1 - \xi_{i-1}(x))\delta_{i,i-1}(x) + \mu \xi_{i-1}(x)\delta_{i,i-1}(x) + (1 - \delta_{i,i-1}(x))$$

Contact process model

- **Network structure: eLasso** (adjusted version of `IsingFit` package in R)
- **parameter: Percolation Indicator (PI)**

$$\hat{\lambda}_t = \frac{U_t}{A_t} \quad \hat{\mu}_t = \frac{D_t}{B_t}$$

Contact process model

- **Network structure: eLasso** (adjusted version of `IsingFit` package in R)
- **parameter: Percolation Indicator (PI)**

$$\hat{\rho}_t = \frac{U_t B_t}{A_t D_t}$$

What do we have?

- Model that describes dynamics
- Fairly good estimate of the Percolation Indicator
- Applying to real data:
 - 1 rapid cycling bipolar patient
 - PANAS scores, daily, 90 days

Results real data

Results real data

- Percolation indicator = 1.84
- t -test: is PI larger than 1?
- $p = 0.22$ ($t = 0.79$, $df = 18$)

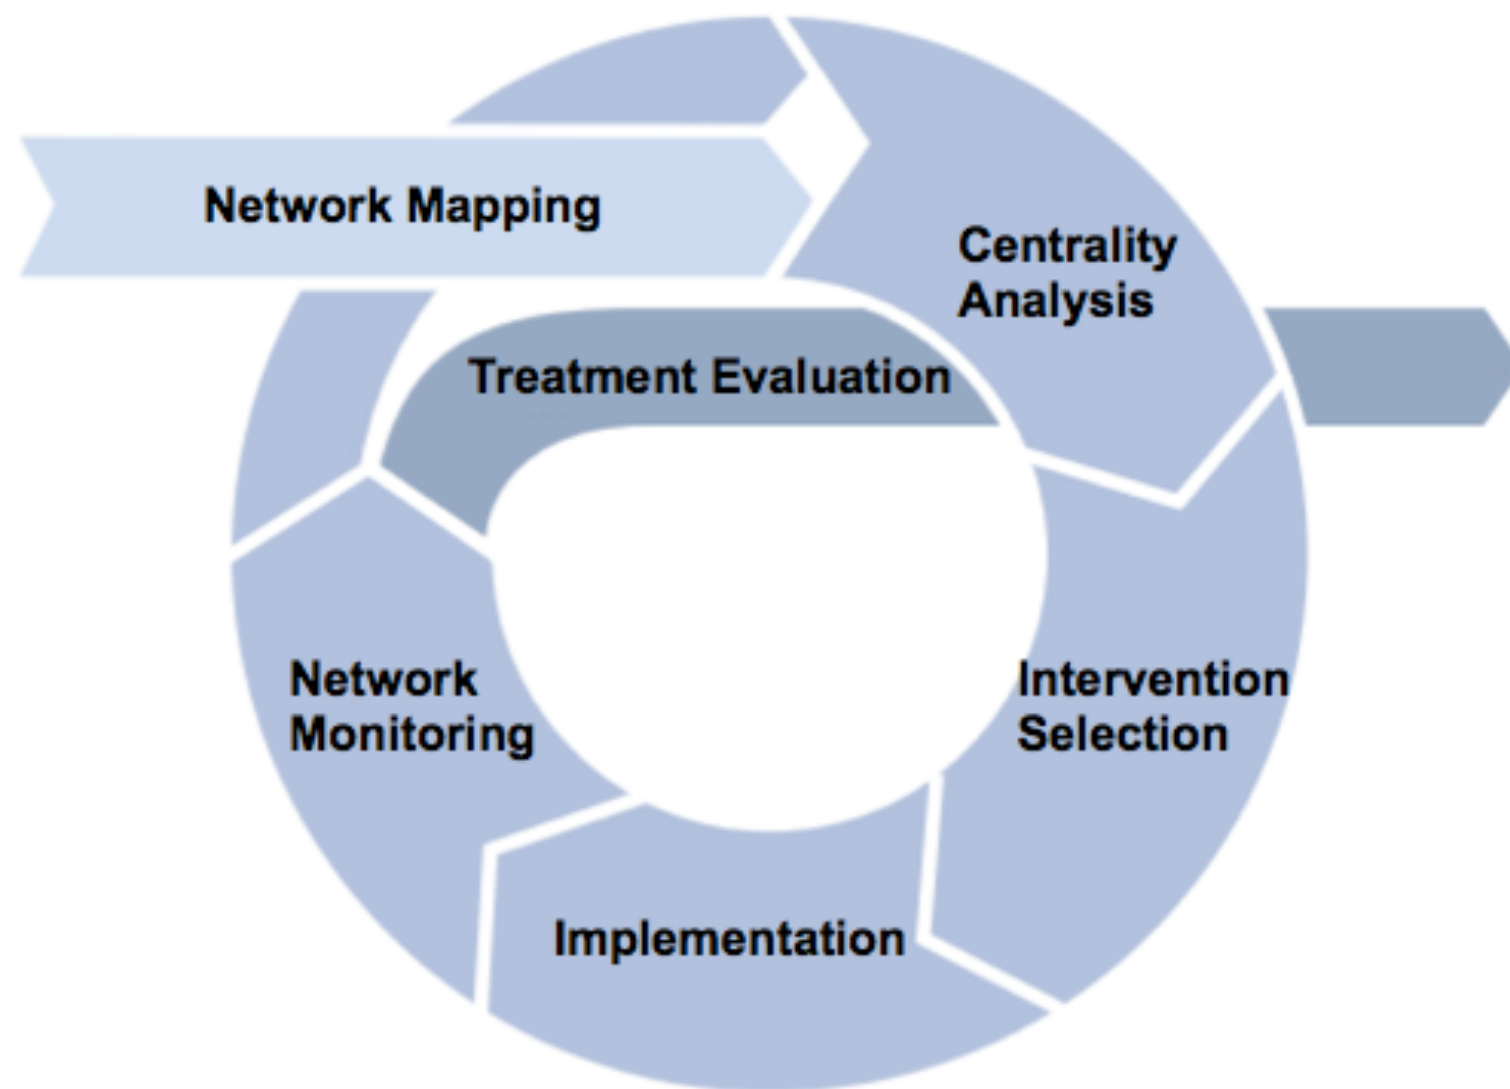

Results real data

- Percolation indicator = 1.84
- t -test: is PI larger than 1?
- $p = 0.22$ ($t = 0.79$, $df = 18$)
- It is **inconclusive** whether infection will continue or die out

What could a clinical application look like?

An integrated tool and process

TWO FICTITIOUS PATIENTS

DOLORES & EDWARD

**Suffering from MD &
GAD symptoms**

STEP 1: NETWORK MAPPING

‘STATIC’ MAPPING

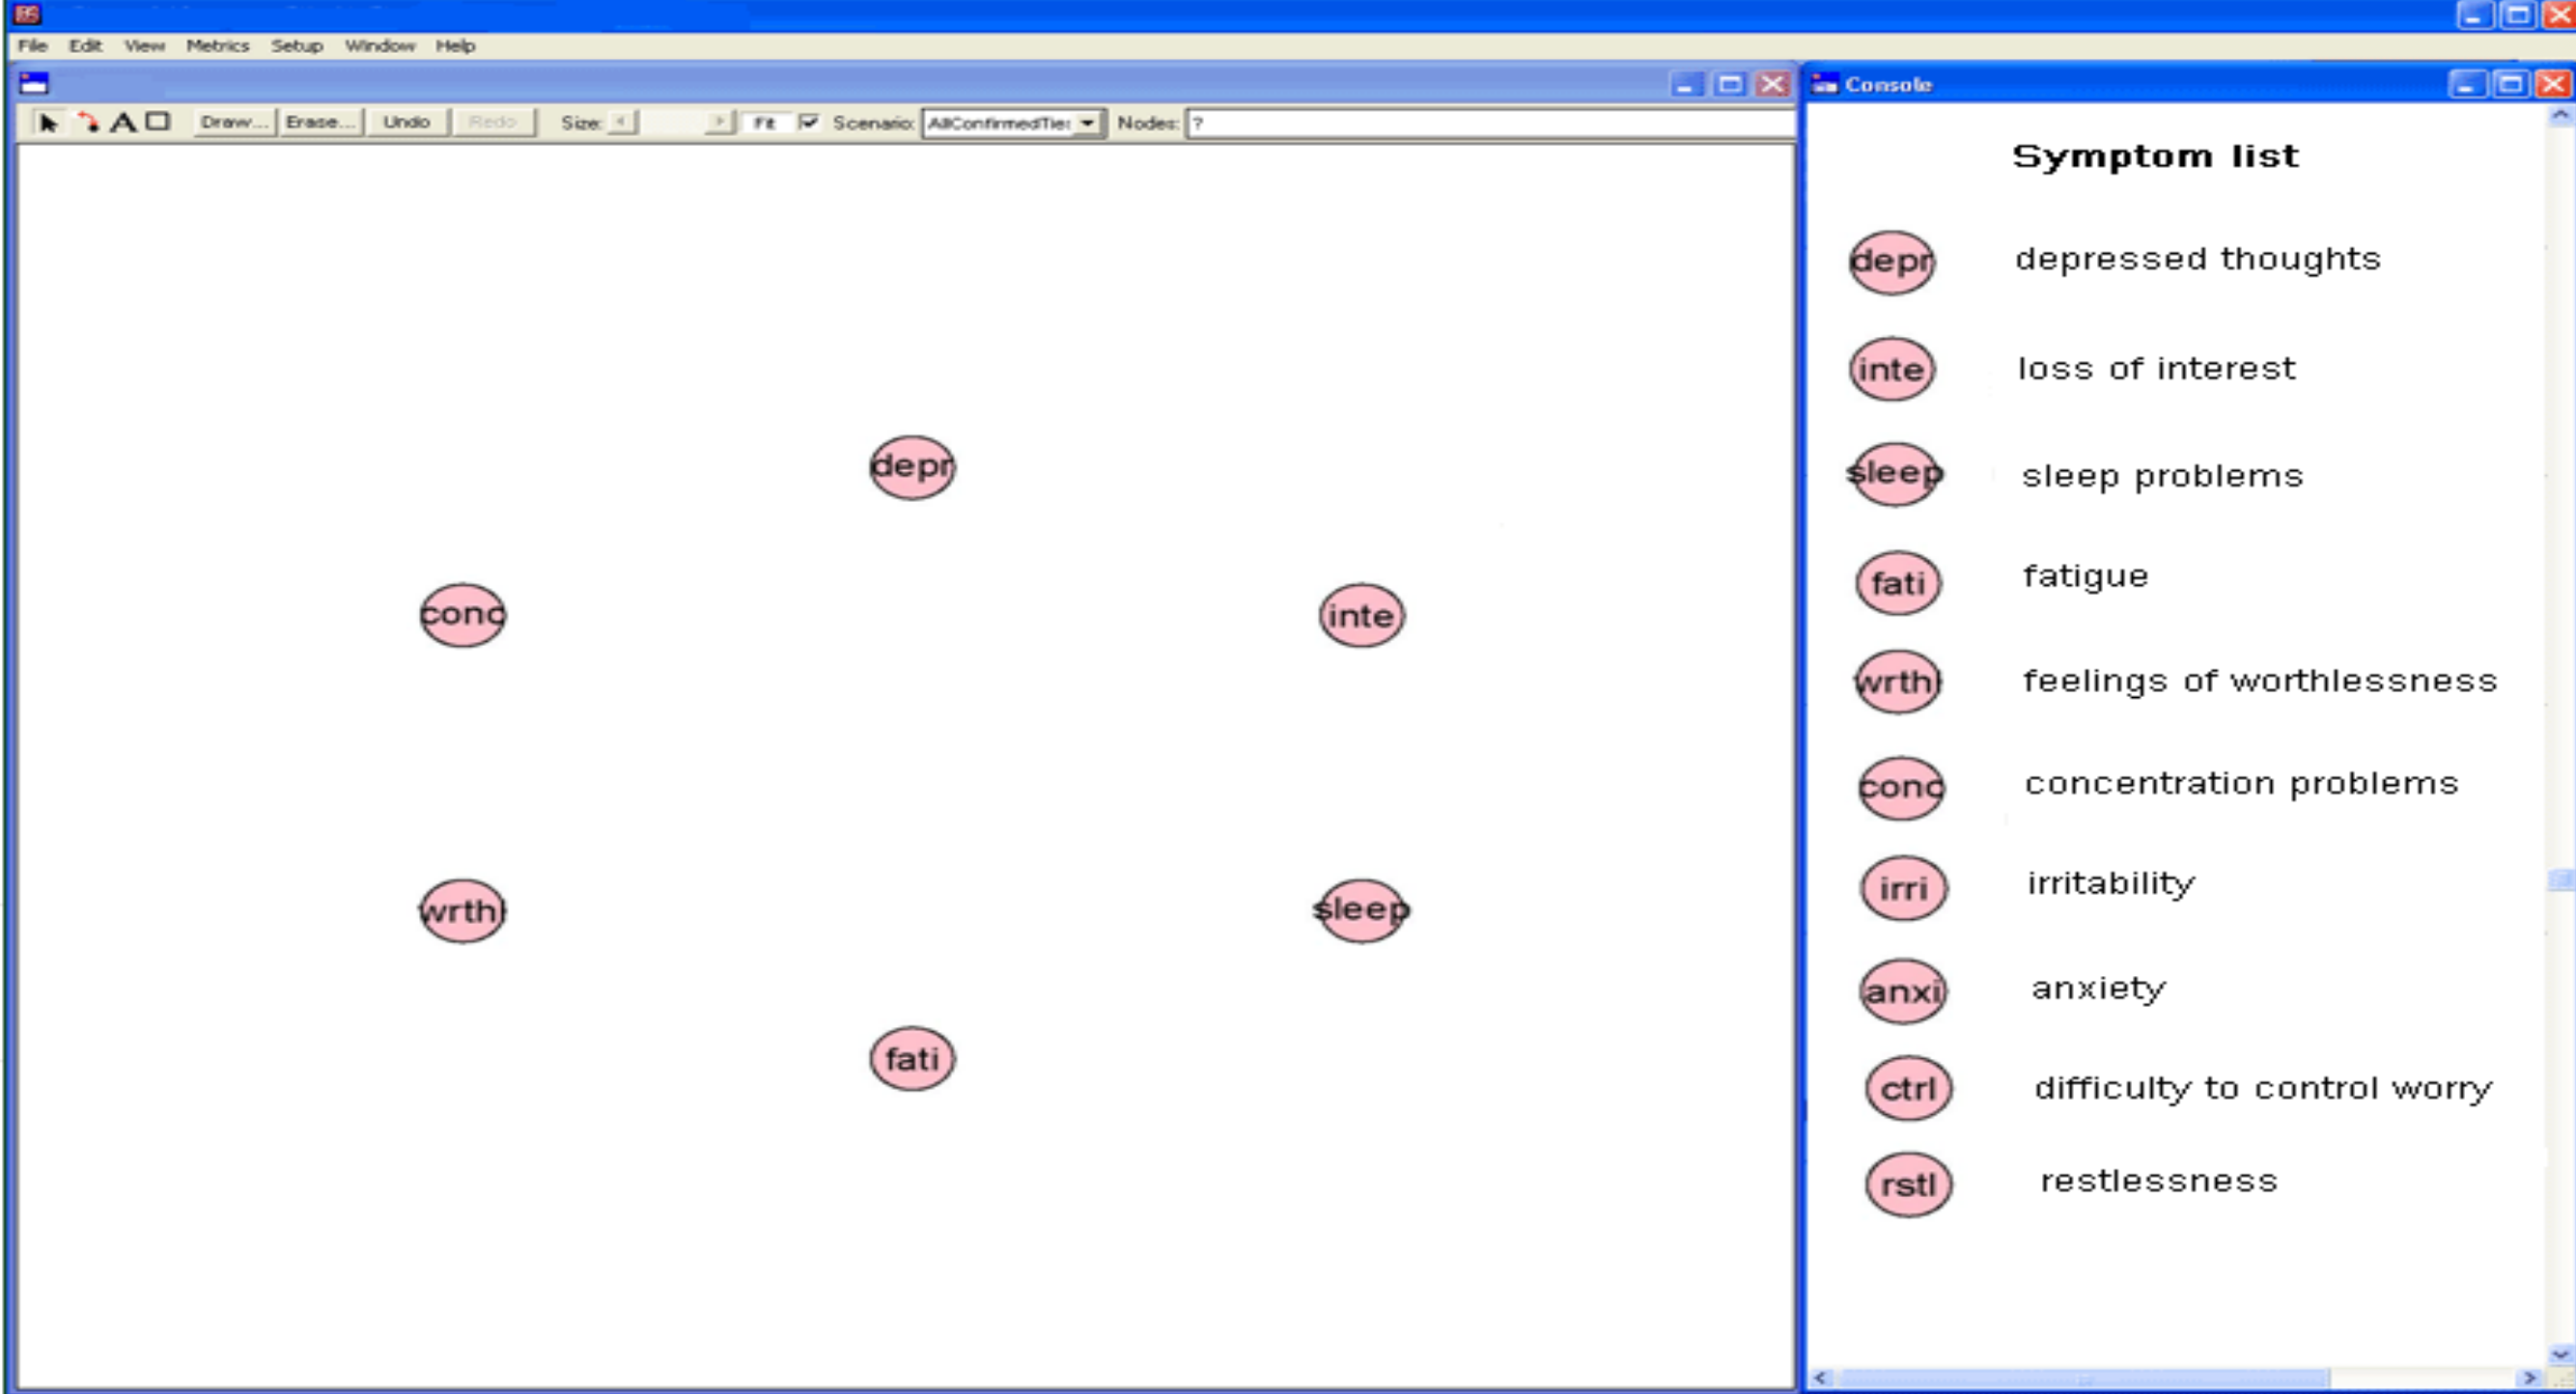

- **Perceived Causal Relationships (PCR) Scale⁹**
- **Assess symptoms present**
- **Perceived causality 1-10**

‘DYNAMIC’ MAPPING

- **Experience Sampling Method (ESM)¹⁰**
- **Assess symptoms present at different time points**
- **Severity on scale**

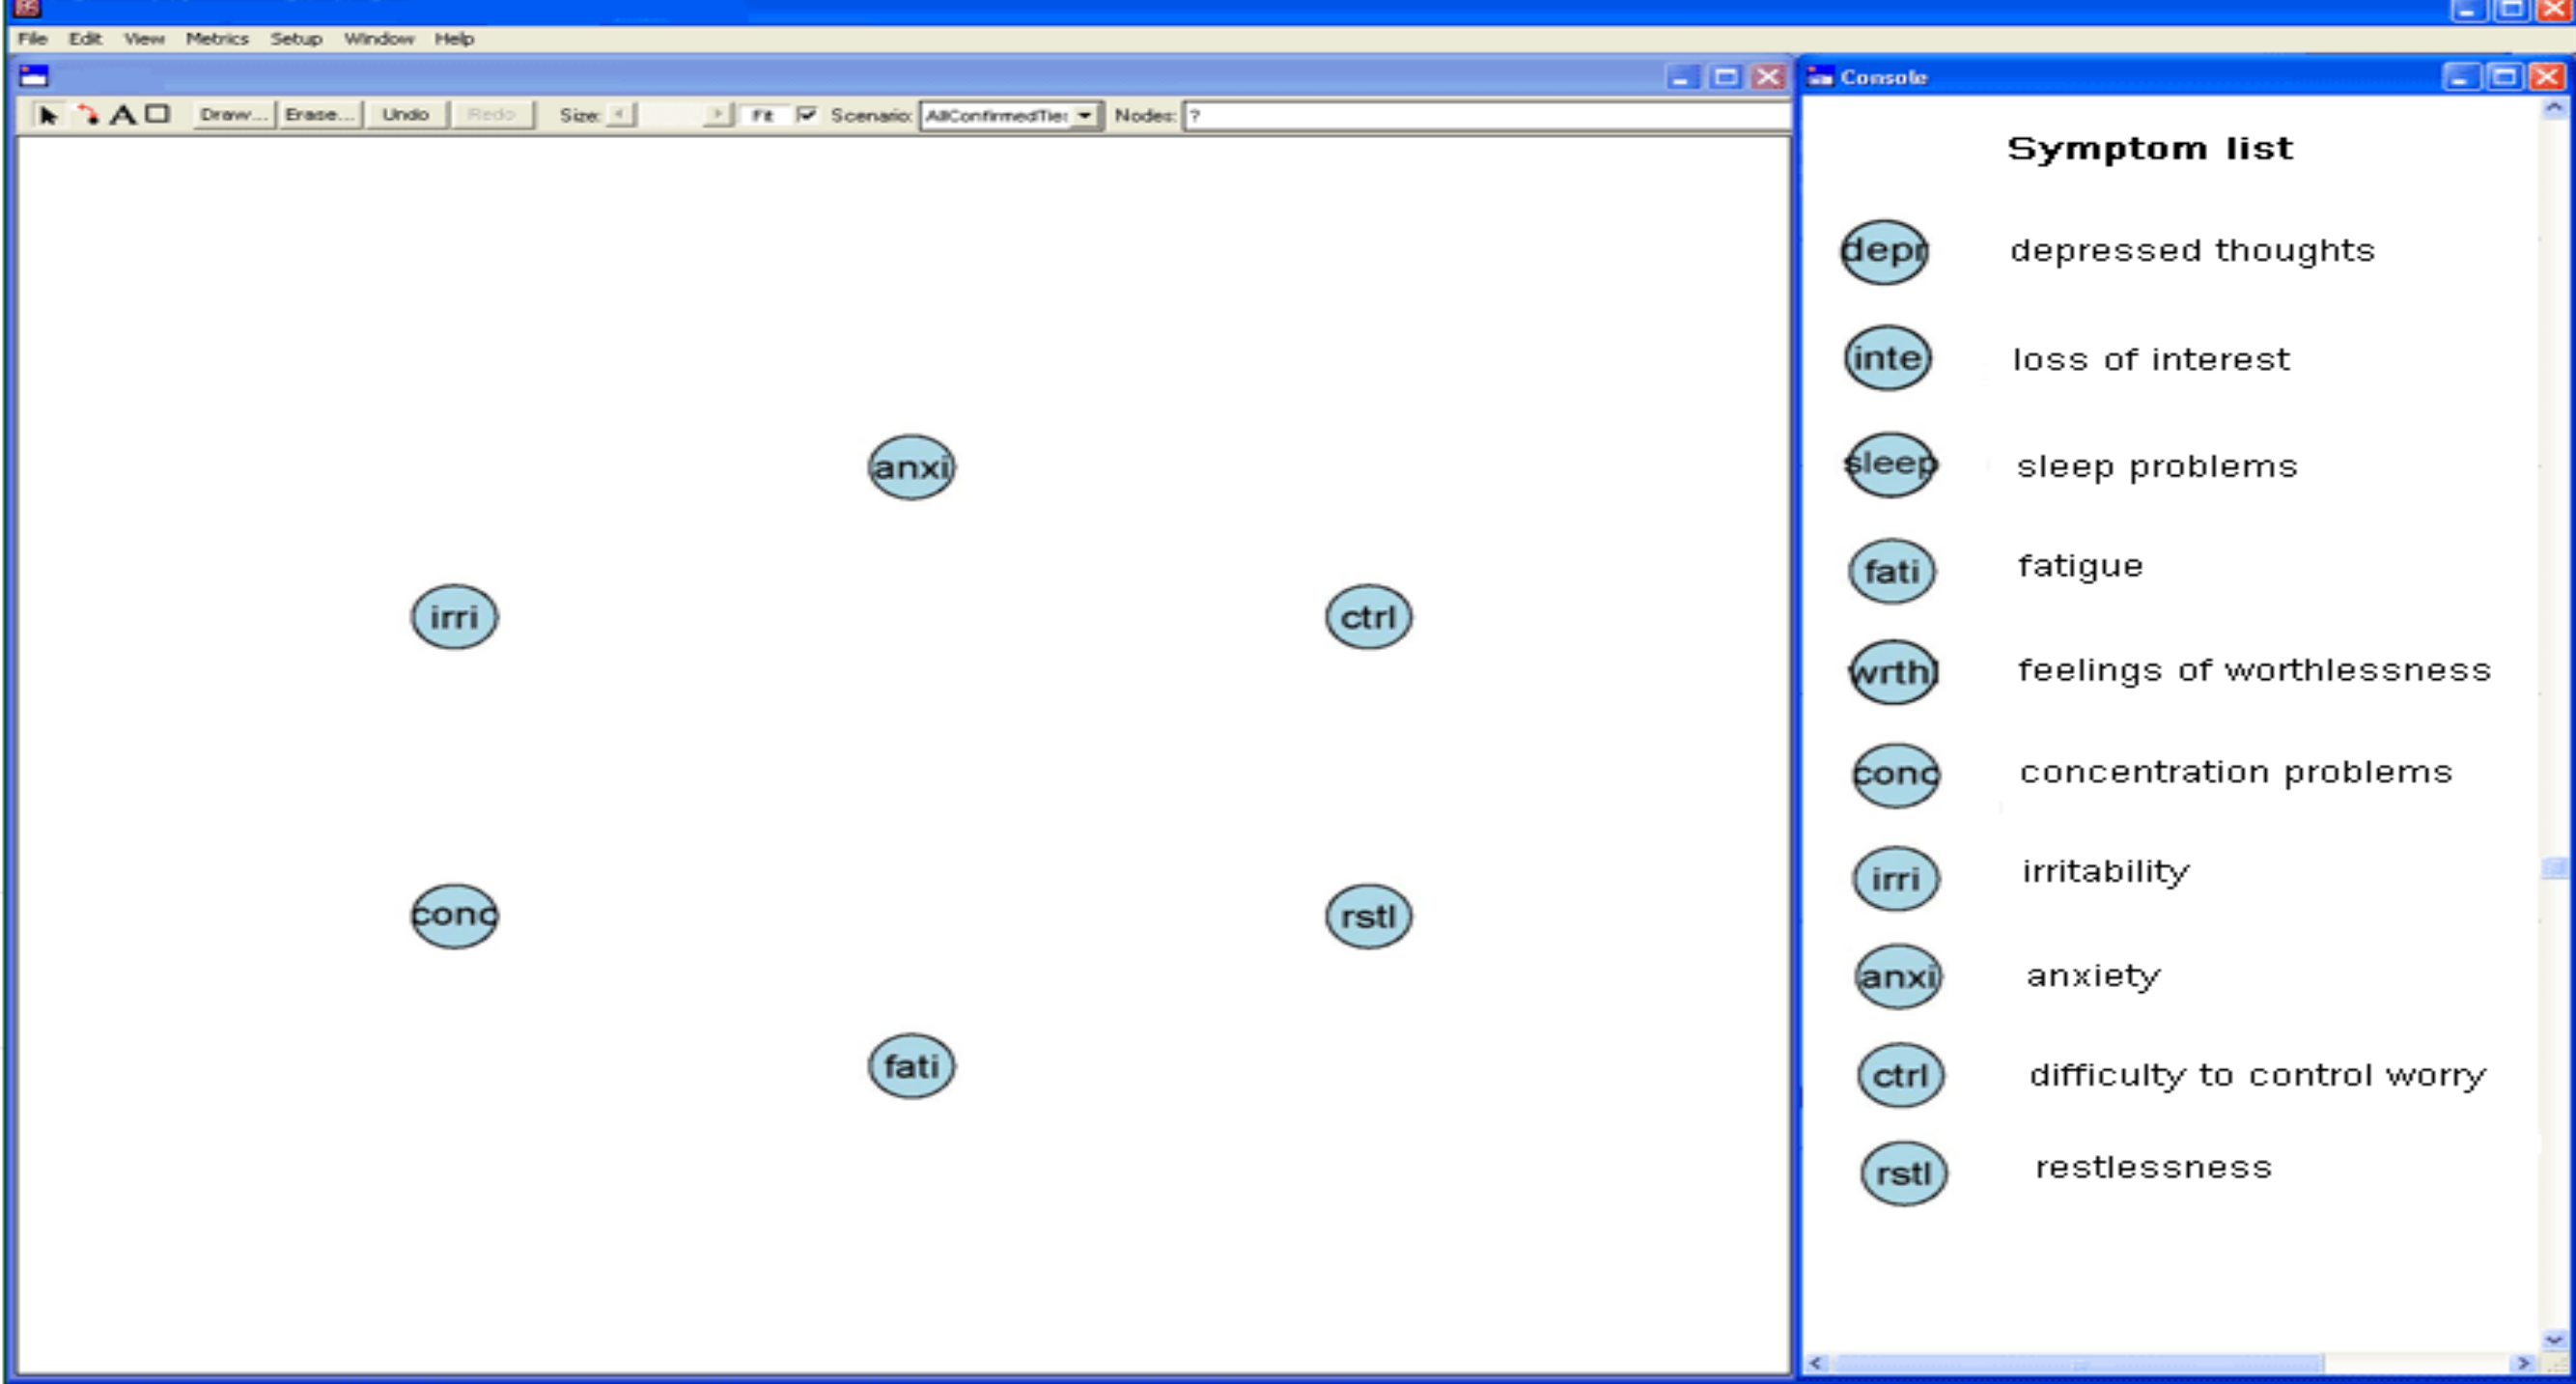

9. Frewen et al. (2012)

10. Bringmann et al. (2013)

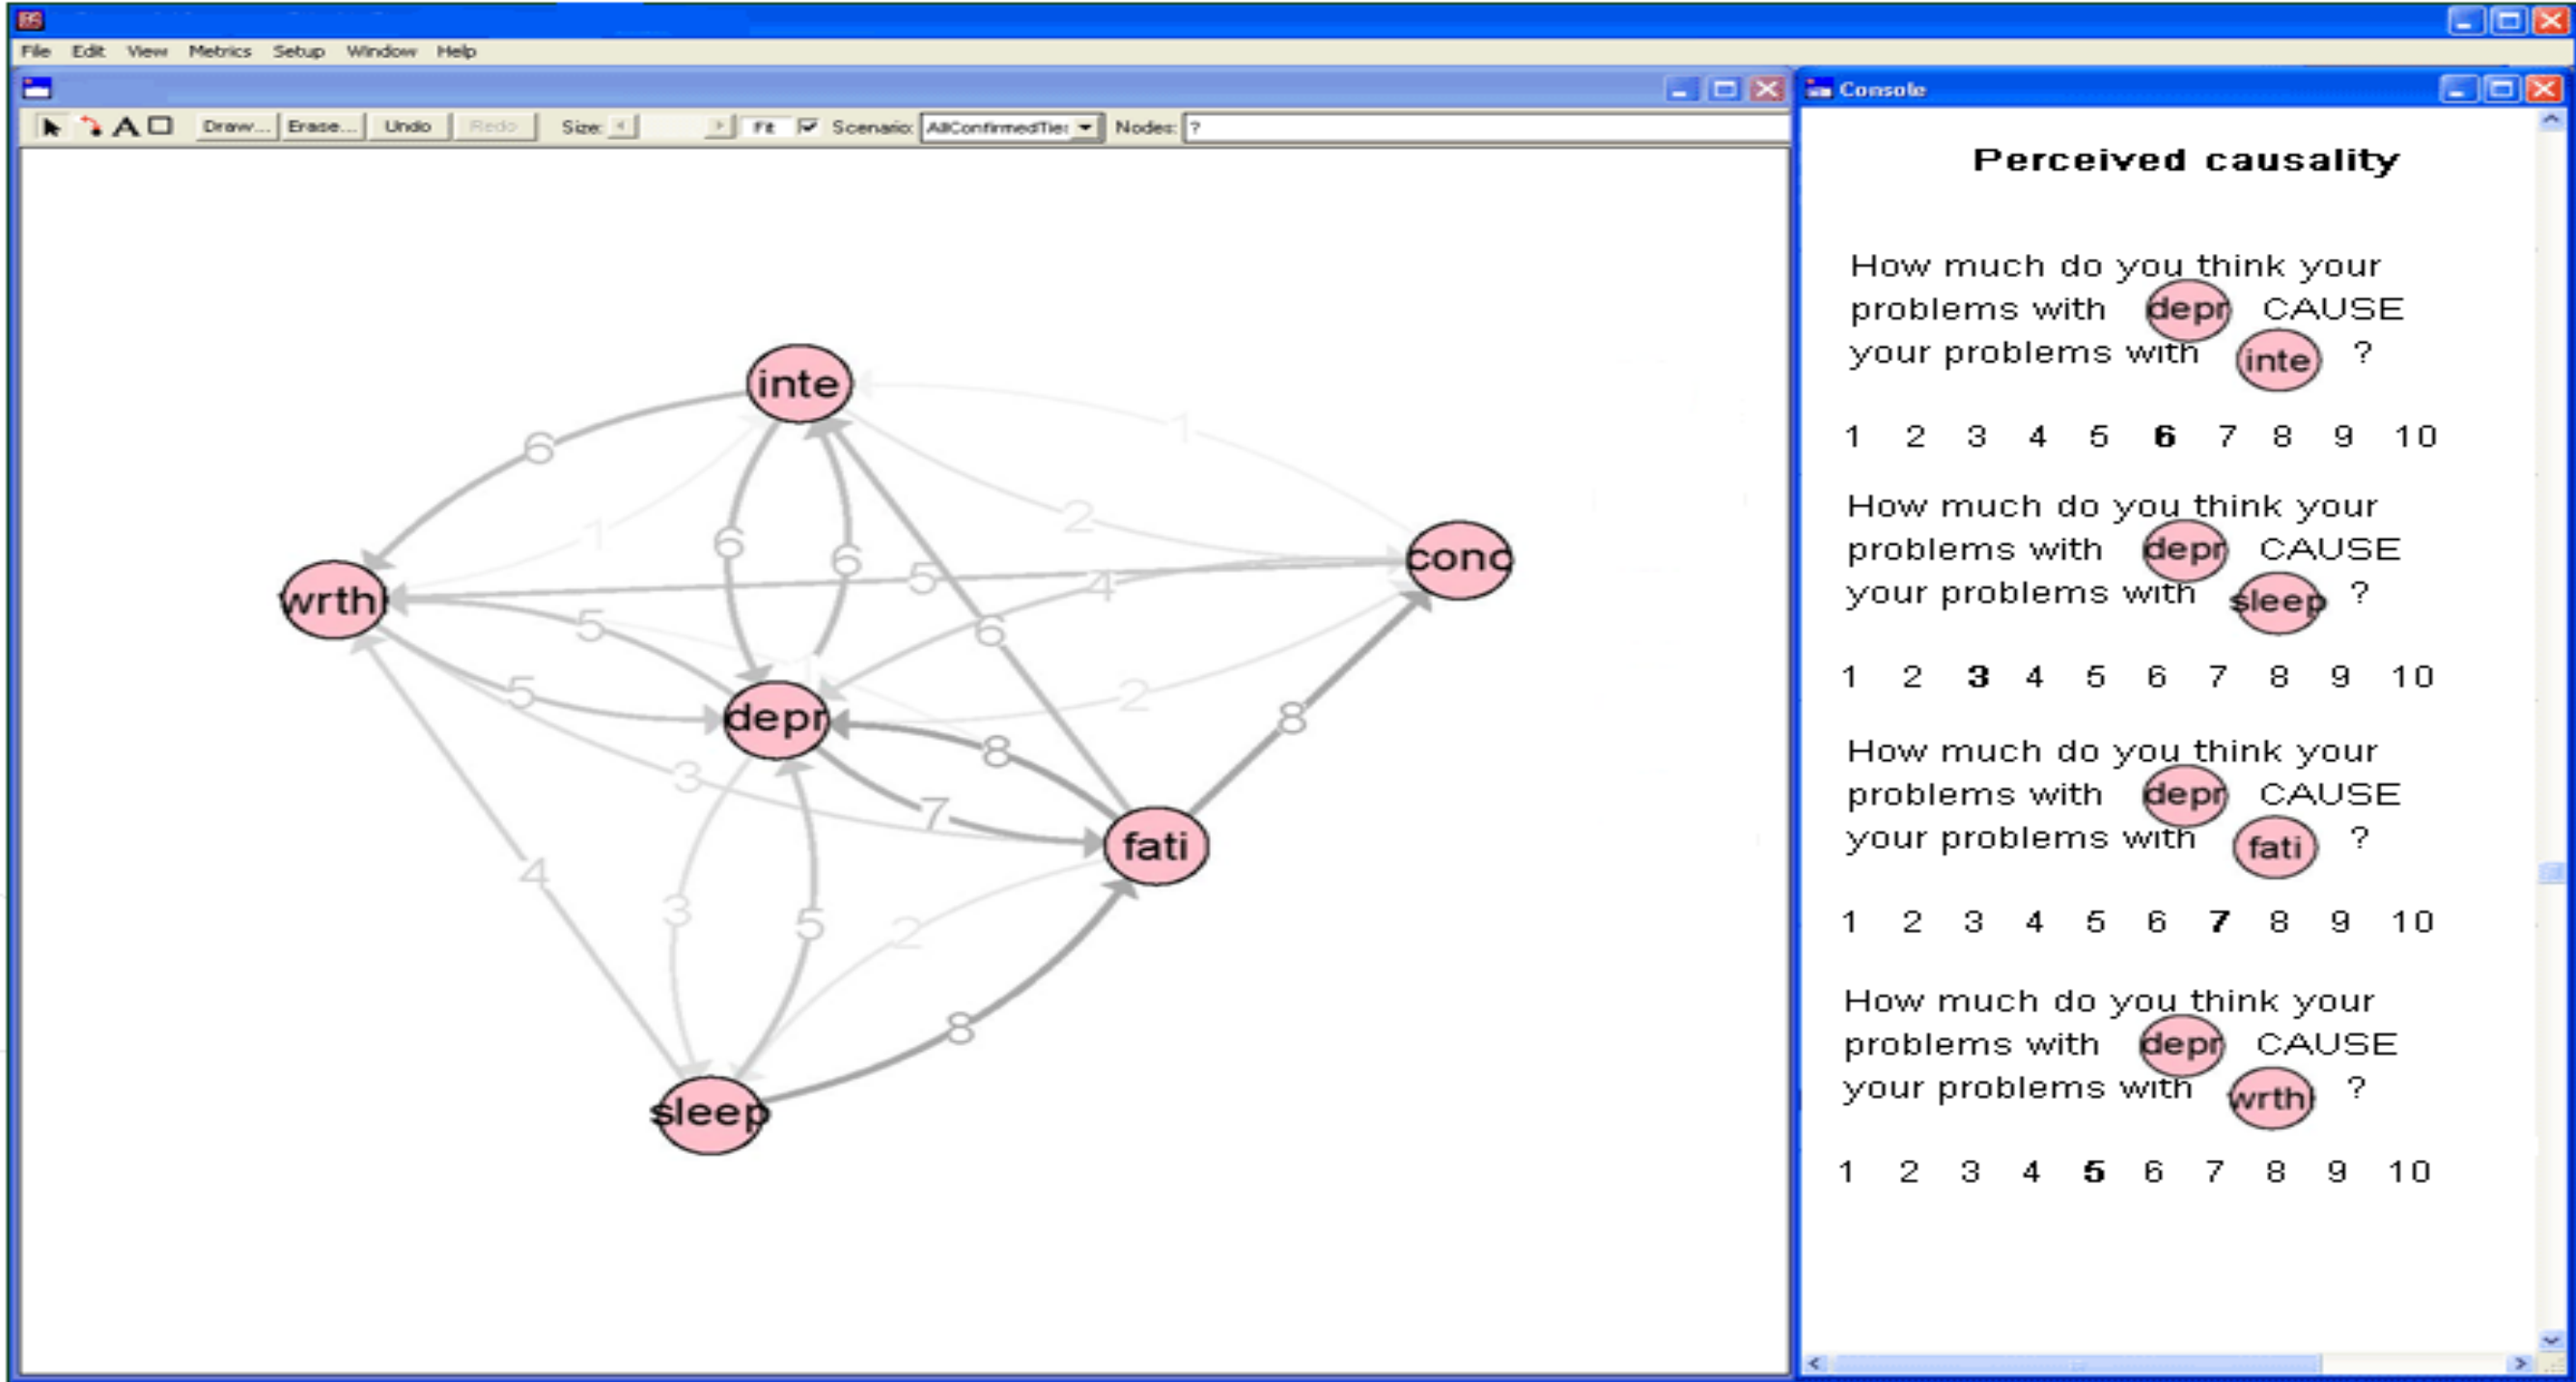

NETWORK MAPPING

First step in mapping Dolores' symptom network

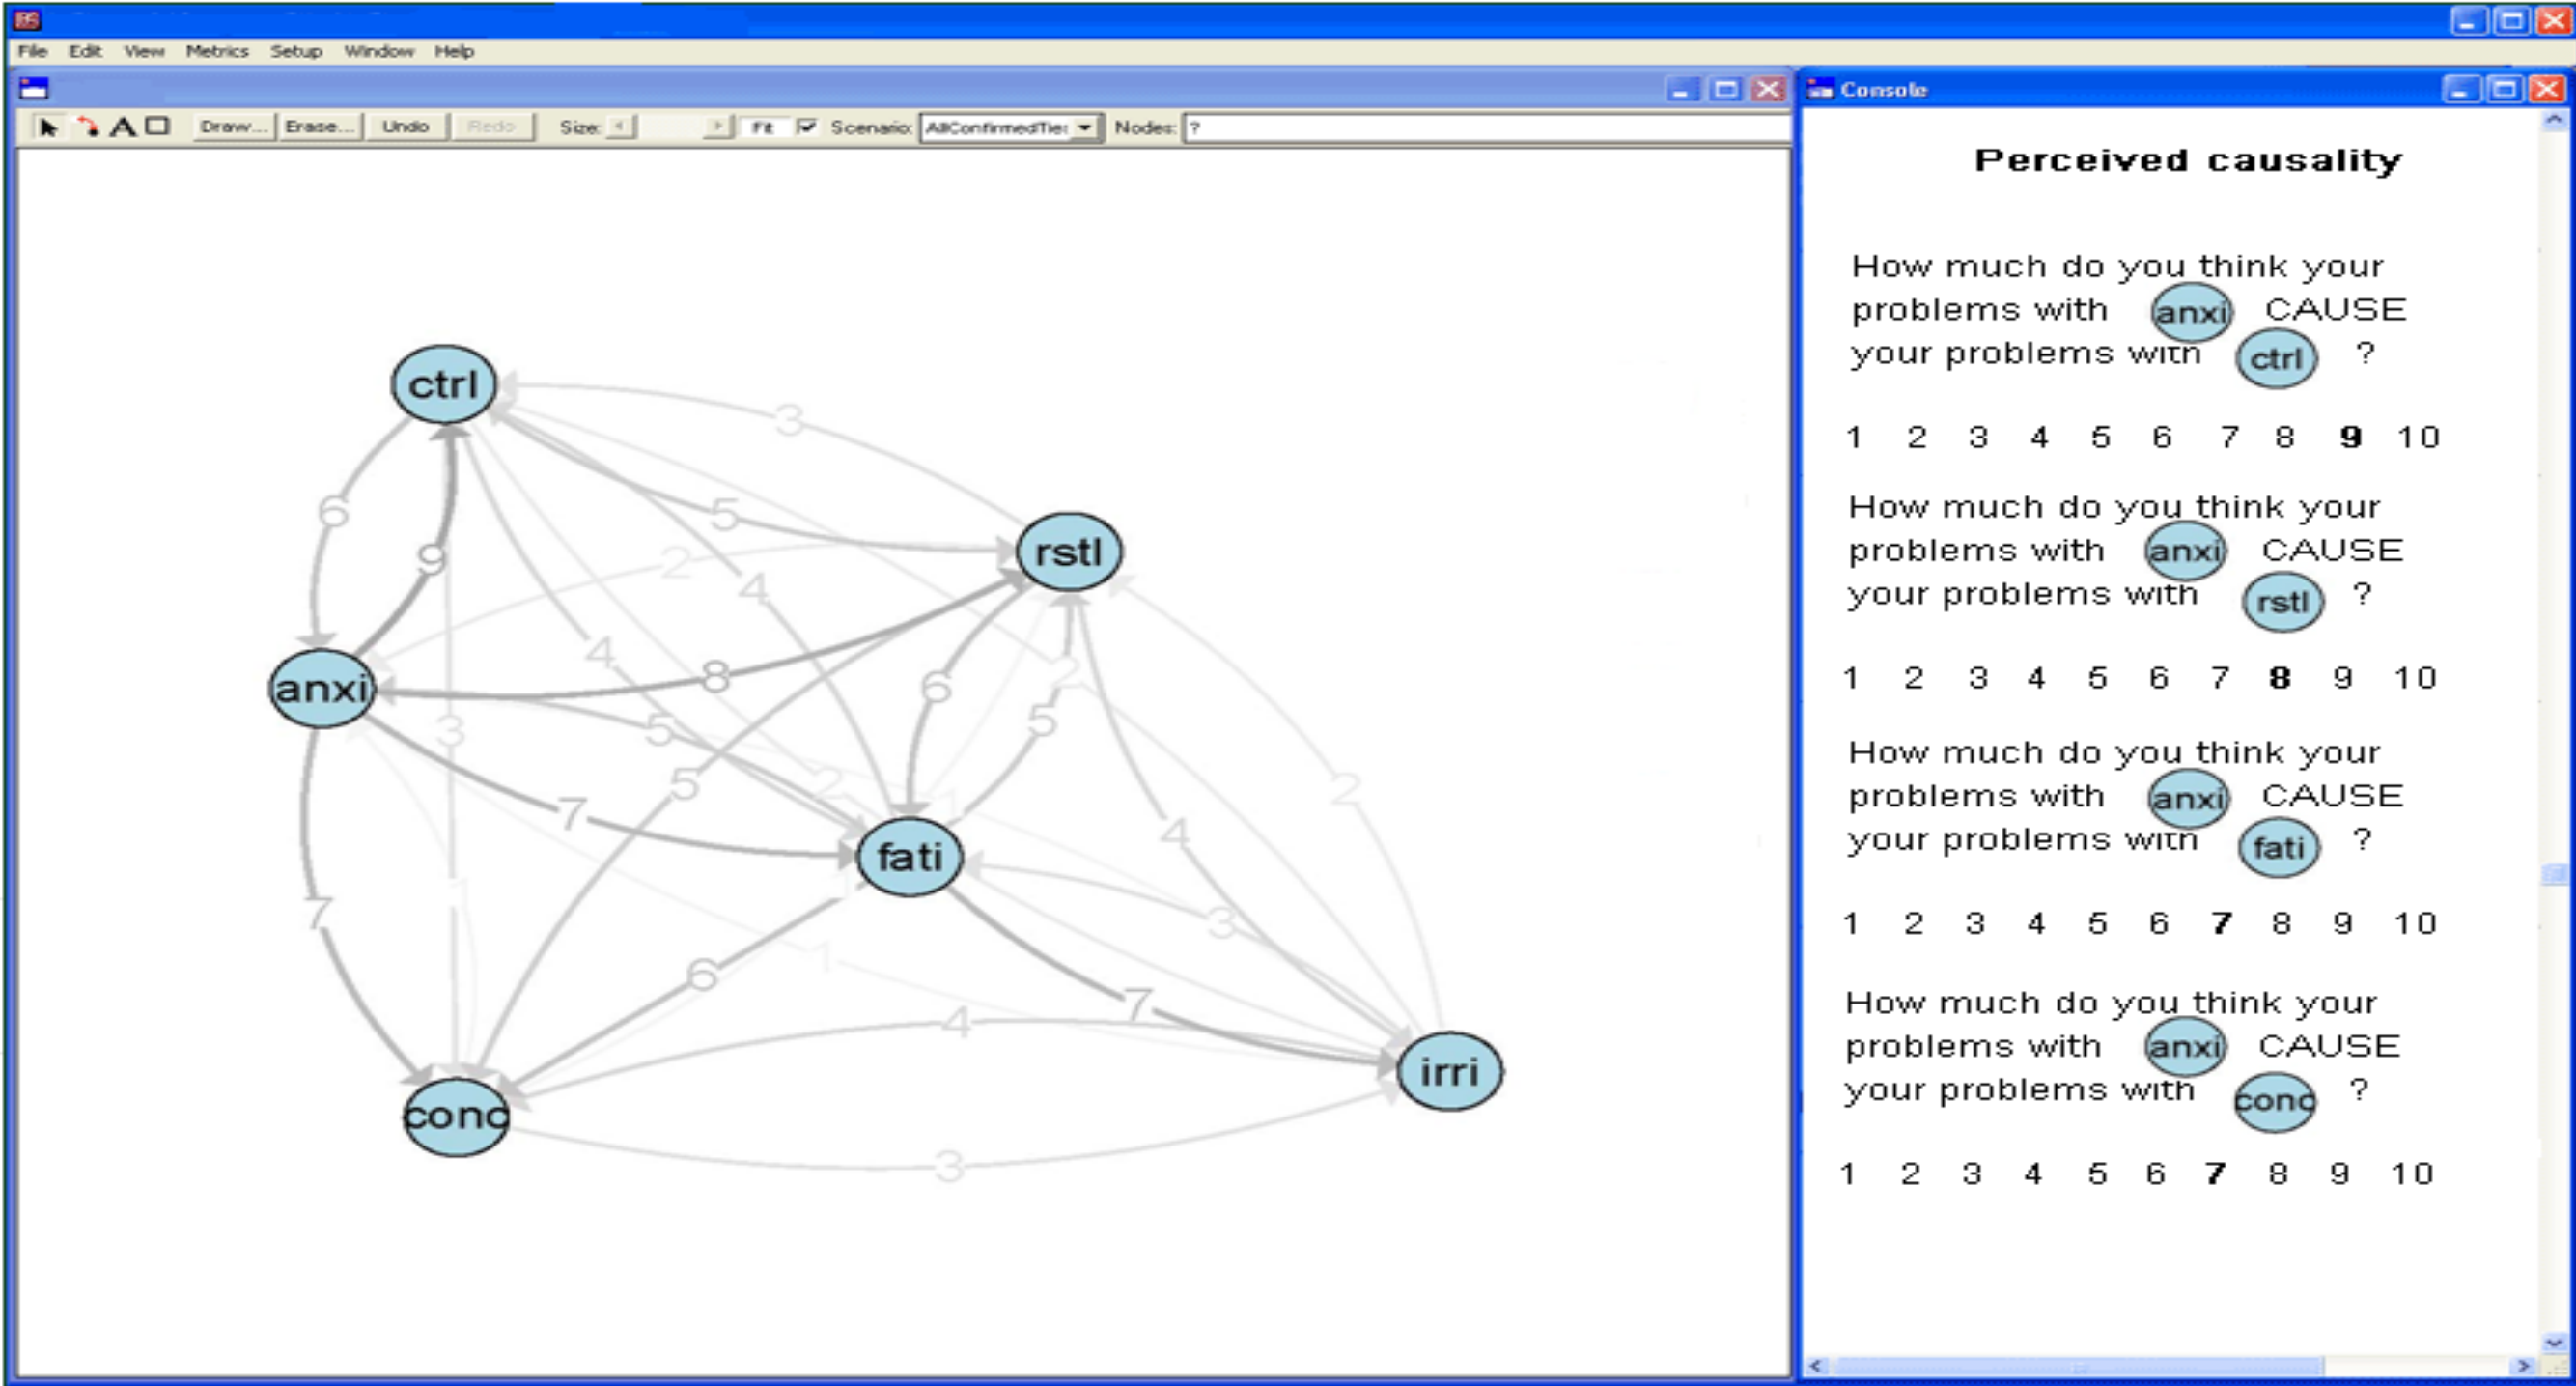

NETWORK MAPPING

First step in mapping Edward's symptom network

NETWORK MAPPING

Adding perceived causal relations to the network of Dolores

NETWORK MAPPING

Perceived causal relations of Edwards compose this network

NETWORK MAPPING

Using a PsyMate¹¹ resembling device or integrated in iPhone/iPad app

STEP 2: CENTRALITY ANALYSIS

BASED ON CAUSE SCORES PCR SCALE

- Calculate mean causal association scores¹²

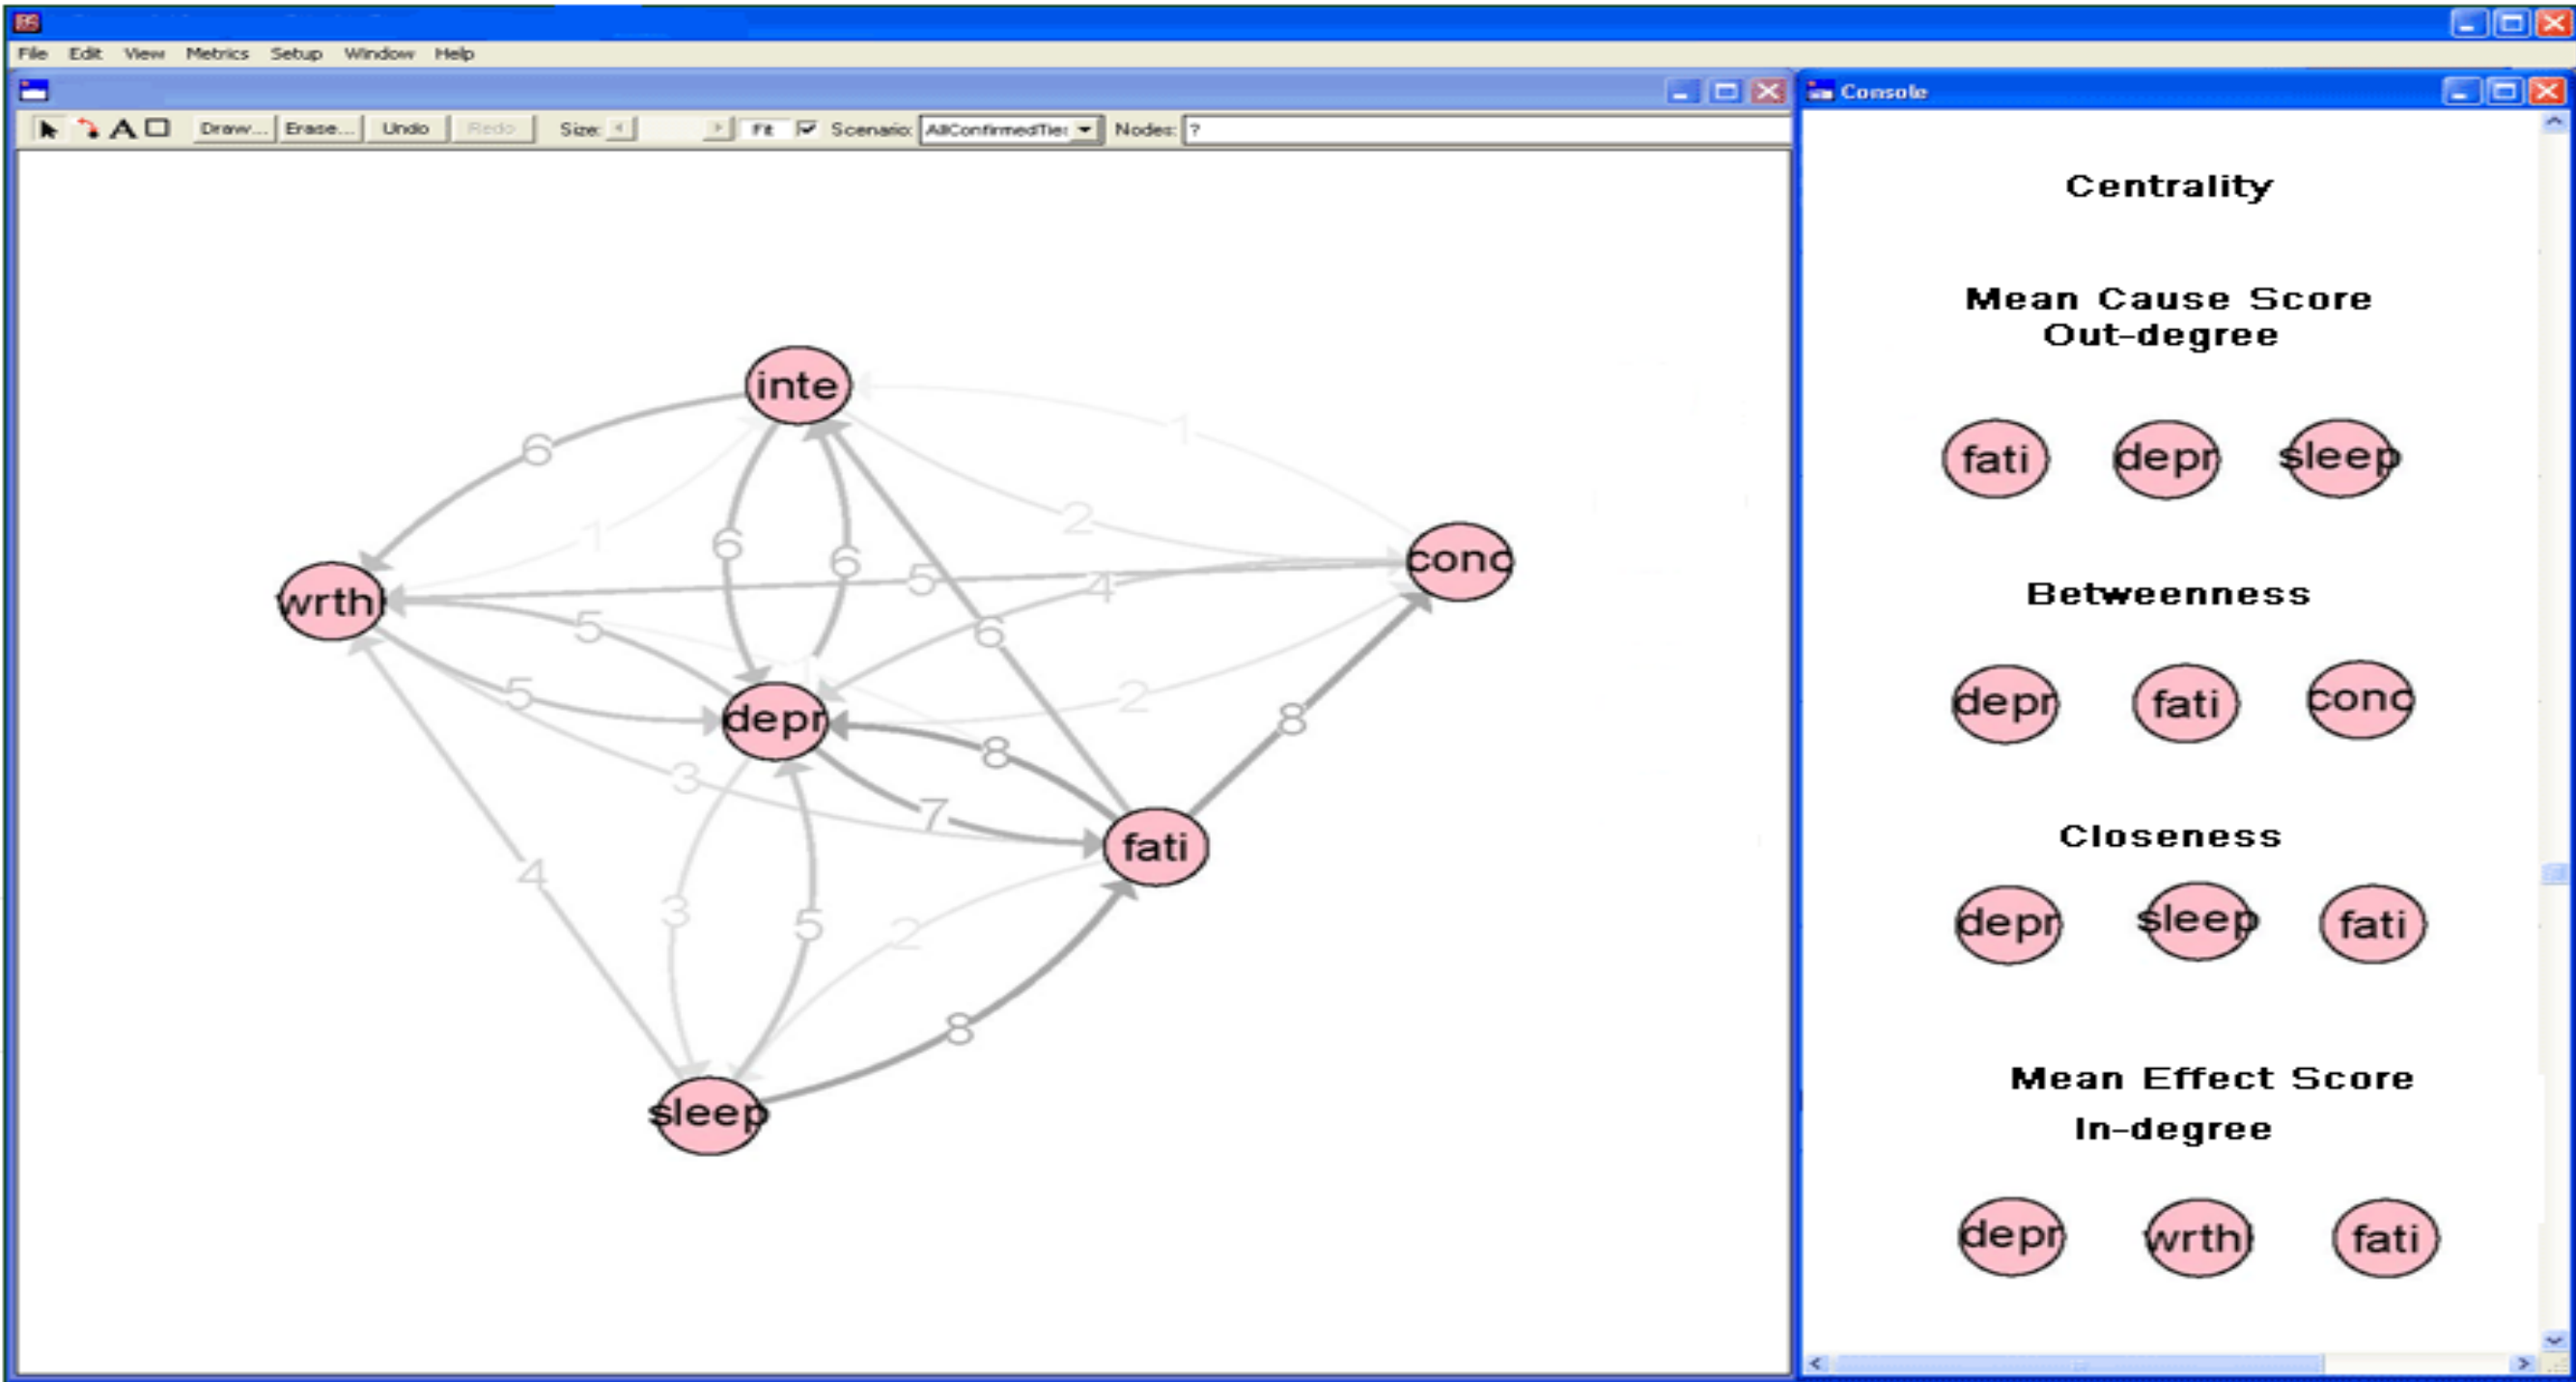

BASED ON NETWORK STRUCTURE

- Degree centrality
- Closeness¹³
- Betweenness¹³
- Eigenvector centrality
- Control centrality¹⁴

12. Frewen et al. (2012)

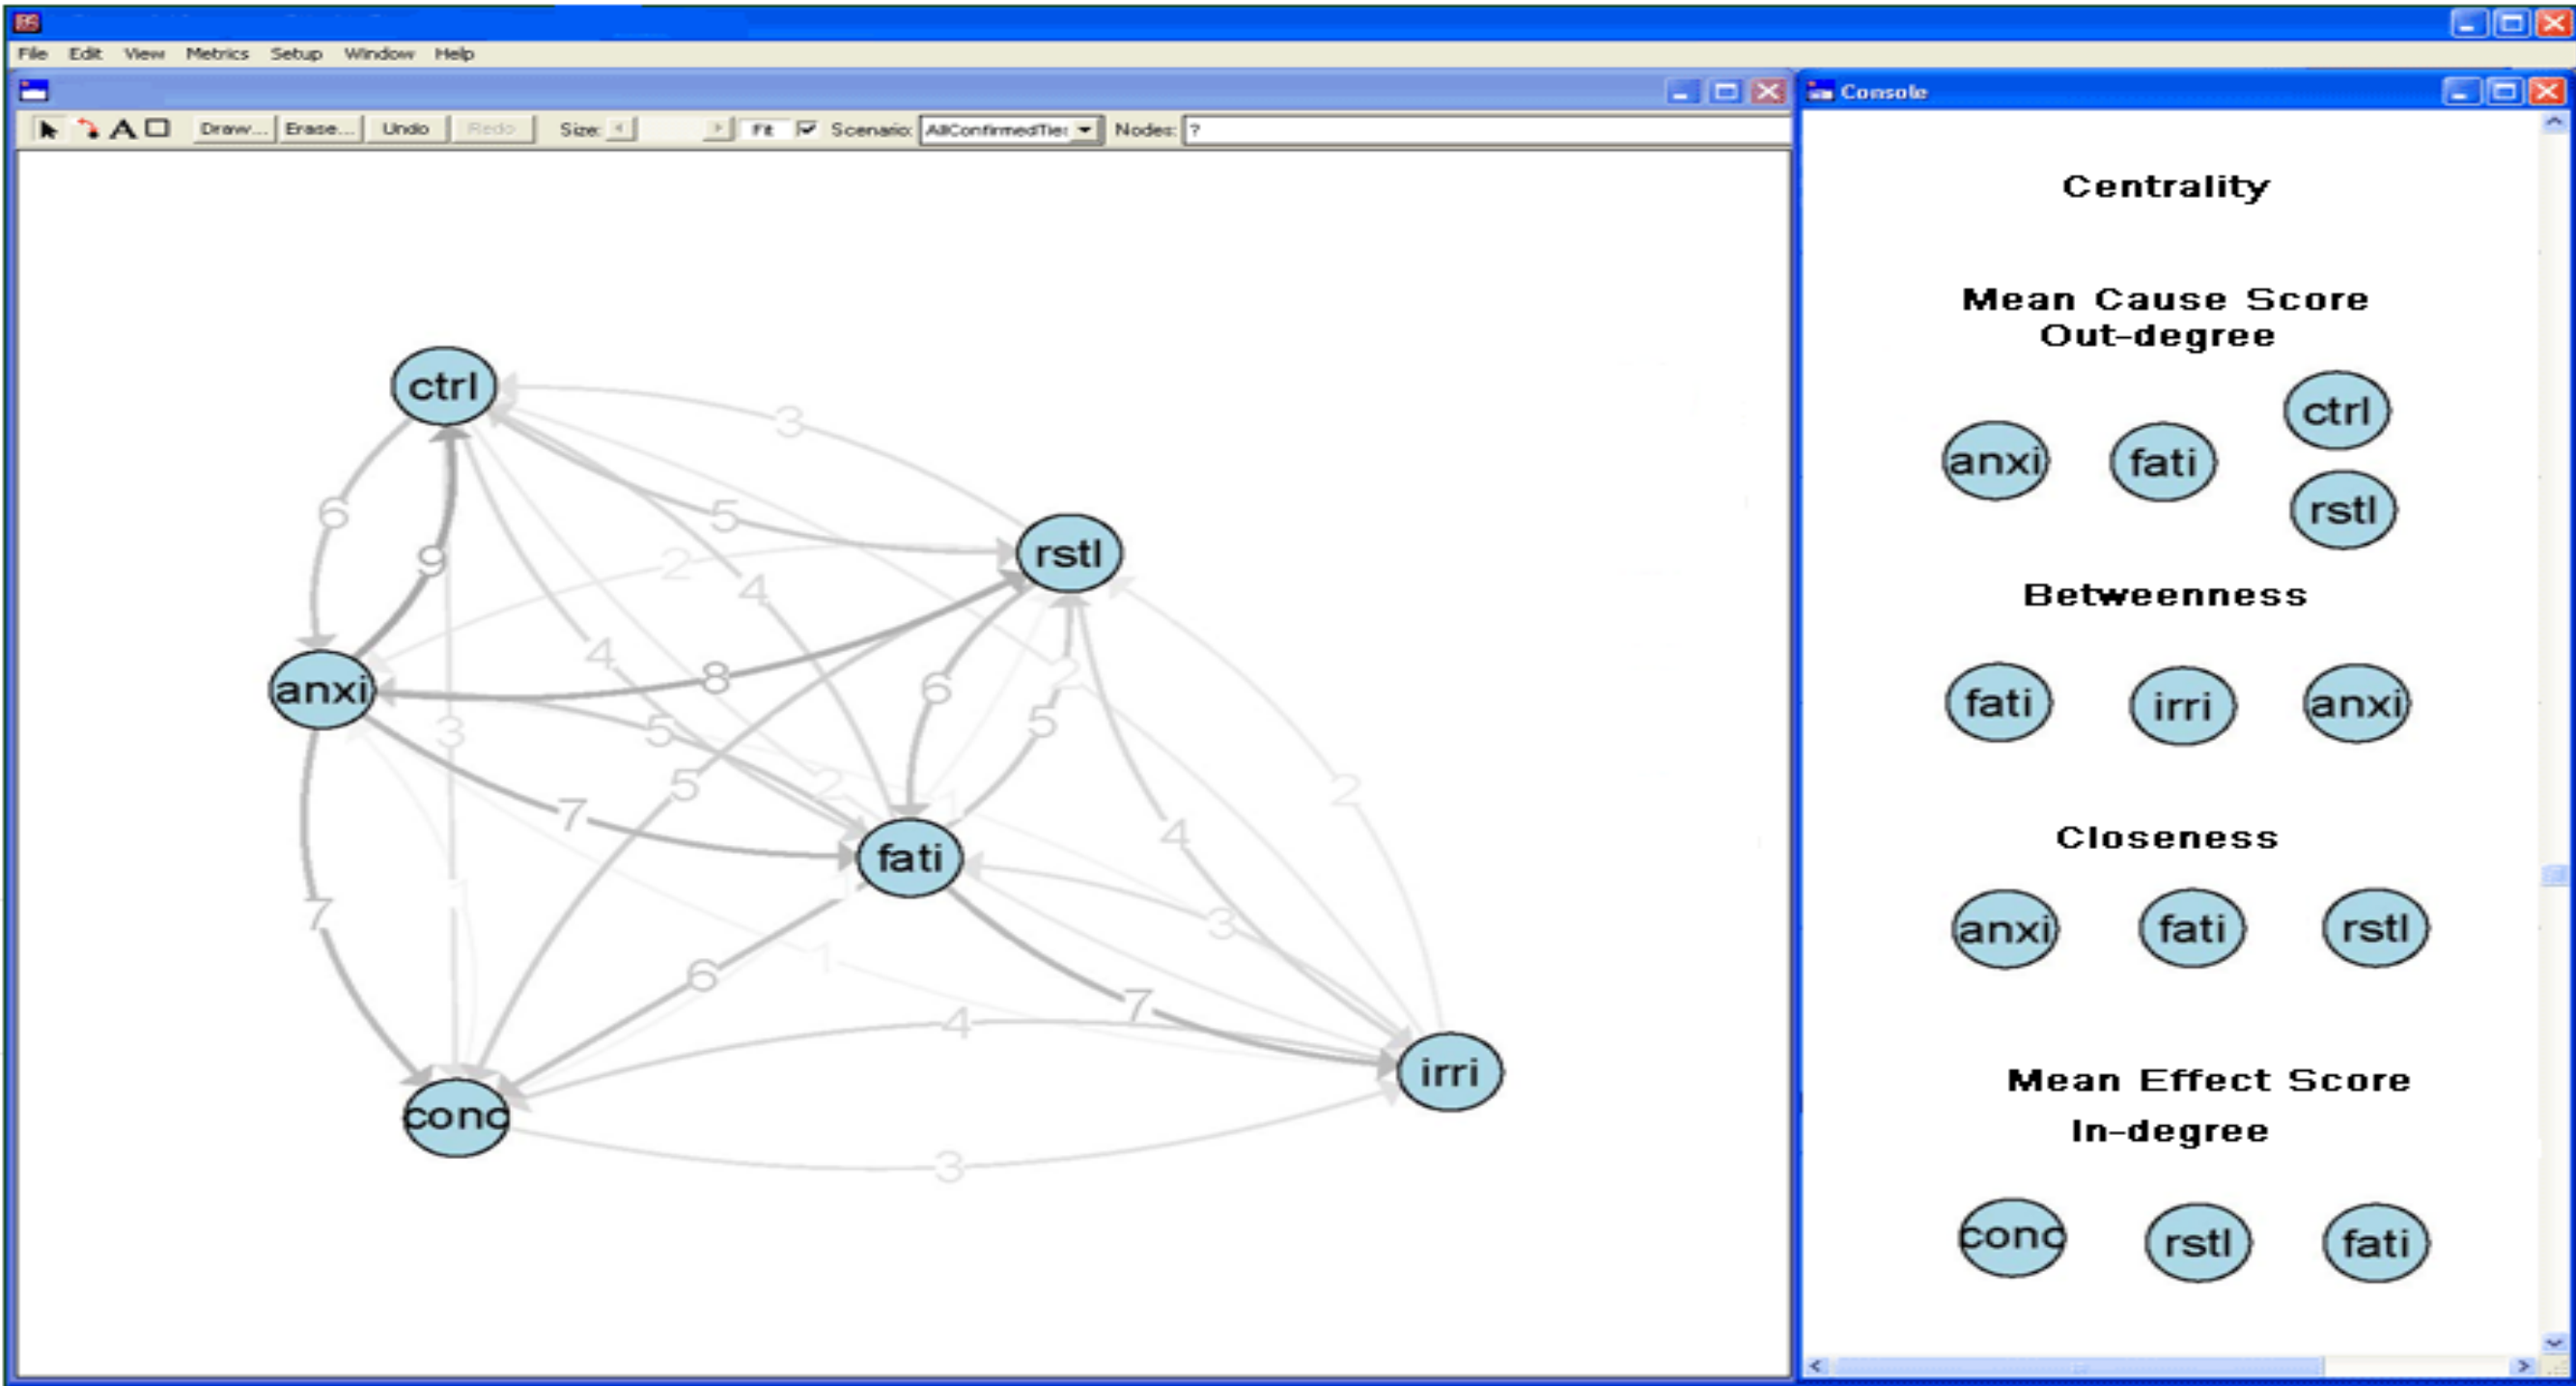

13. Opsahl et al. (2010)

14. Liu, Slotine & Barabasi (2012)

CENTRALITY ANALYSIS

Top-3 central symptoms provided for Dolores

CENTRALITY ANALYSIS

Top-3 central symptoms provided for Edward

STEP 3: SELECTING INTERVENTIONS

- **Systematic Treatment Selection (STS)¹⁵**
- **Mini-interventions¹⁶**
- **For both patients: sleep or cognitive-behavioral interventions**

15. Norcross & Beutler, 2005

16. <http://www.trimbos.org/news/trimbos-news/symptom-oriented-mini-interventions-sleeplessness-worry-and-stress>

STEP 4:

IMPLEMENTATION

TECHNICAL SKILLS OF THERAPIST

- Executing interventions
- Connecting them to patient's context
- Network education

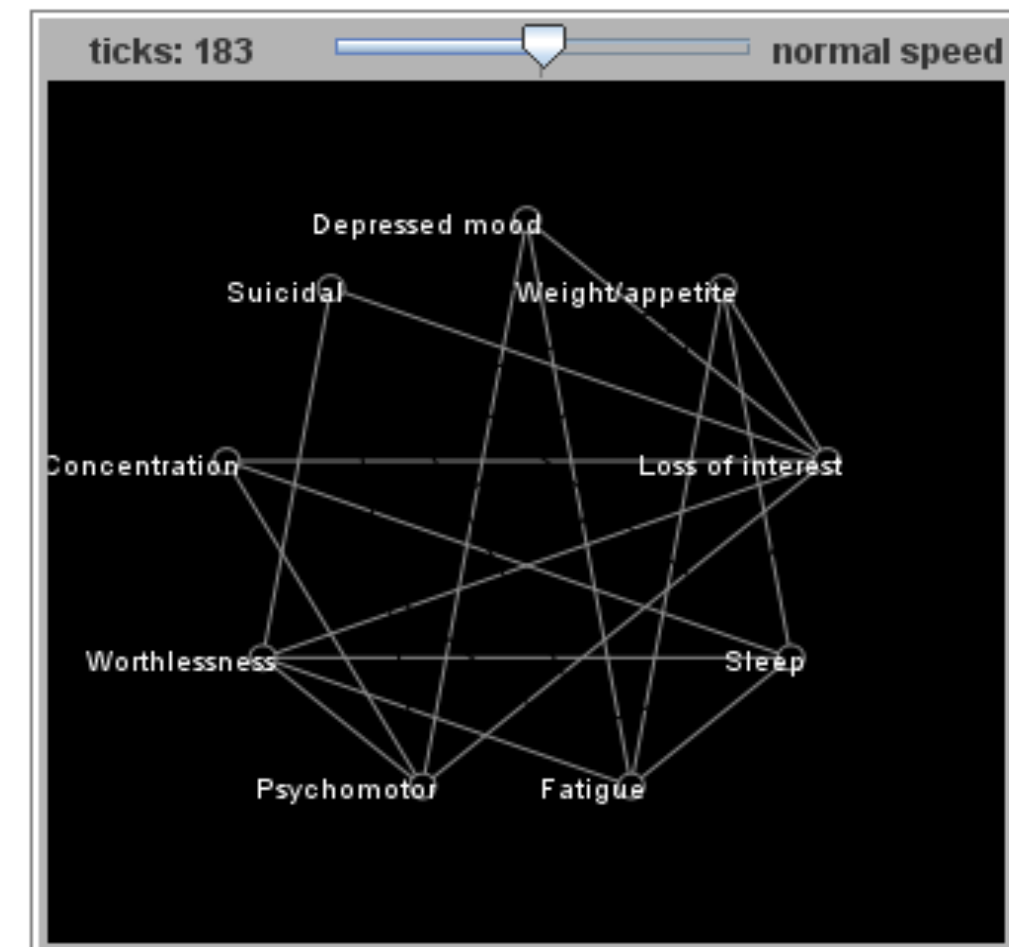

THERAPEUTIC RELATIONSHIP¹⁷

STEP 5: MONITORING THE NETWORK

Detect early warning signals

- Autocorrelation¹⁸
- Variance¹⁸
- Growing dynamic causal impact over time¹⁹

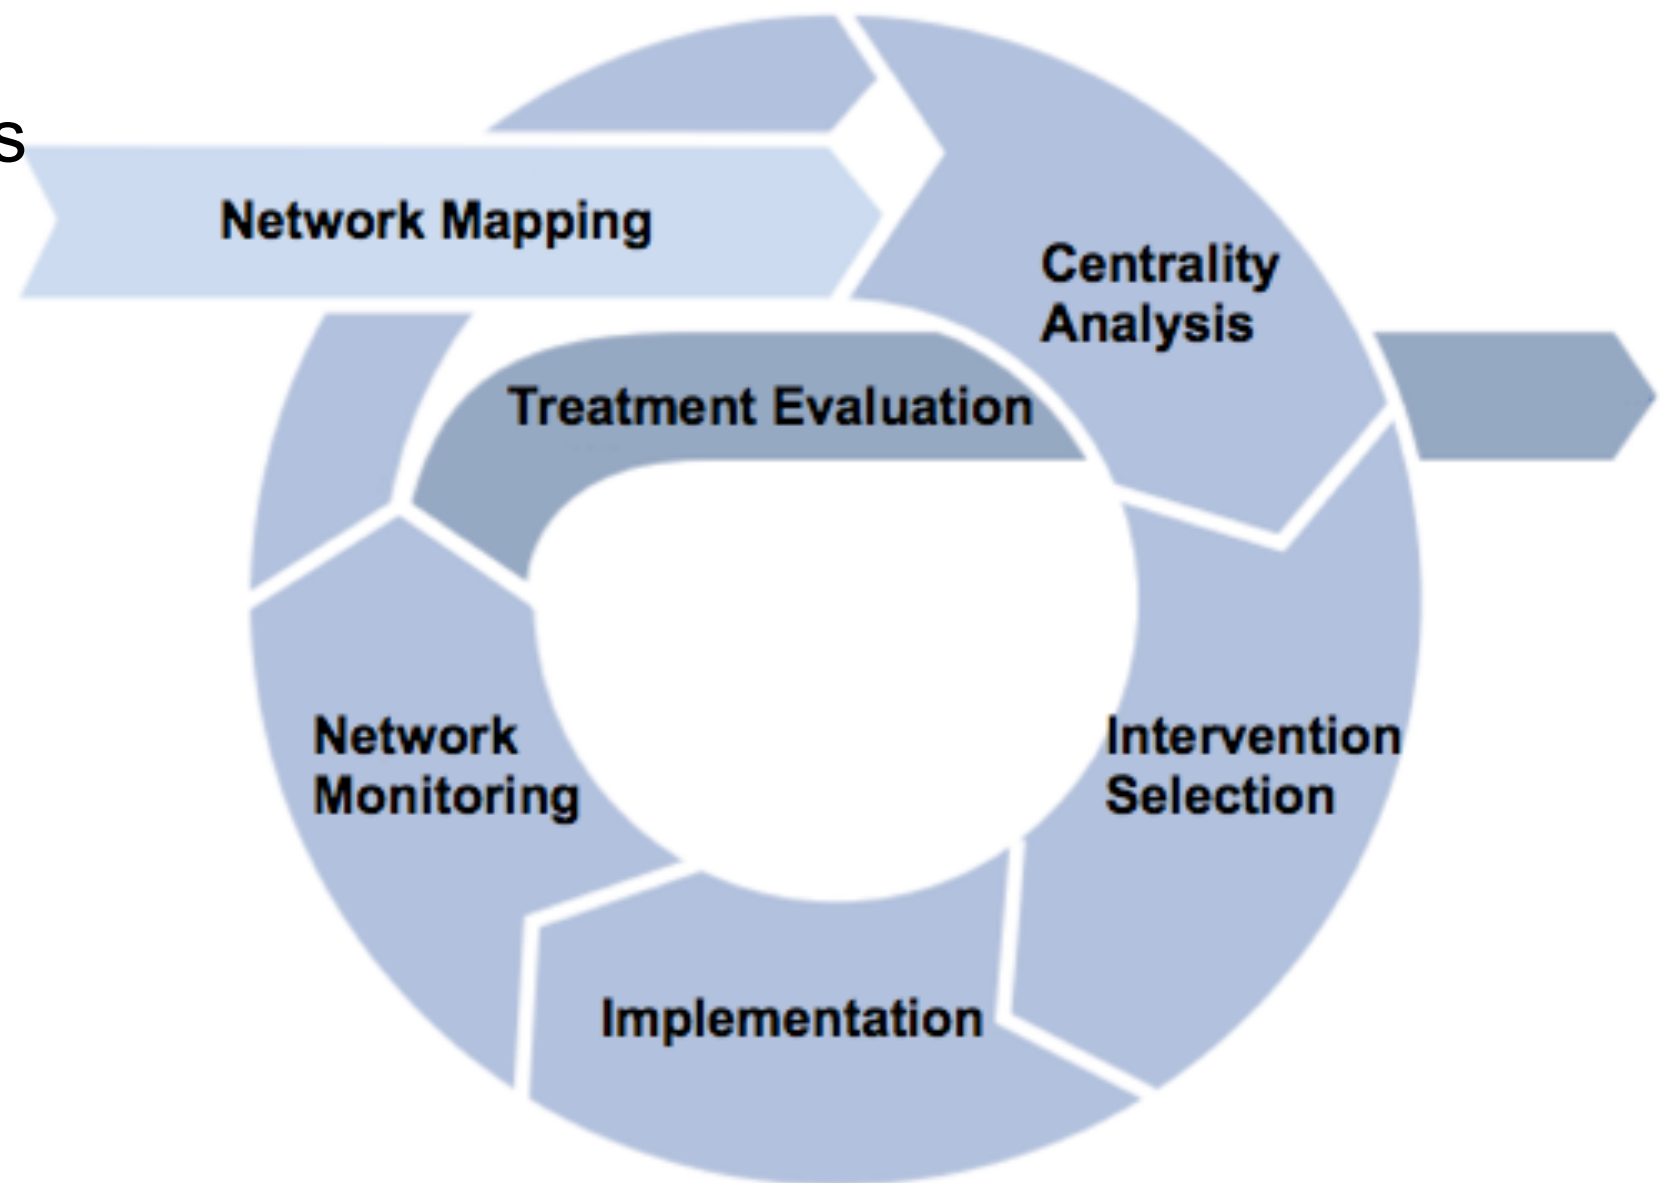

18. Dakos et al. (2012)

19. Wigman et al. (2013)

STEP 6: EVALUATING TREATMENT

Insightful for both

- **Therapist**
 - Effectiveness of chosen interventions
 - Dynamics constituting mental disorders
- **And patient**
 - Awareness of personal symptom dynamics
 - Sense of agency
